Database Technology

Topic 11: Database Recovery

Olaf Hartig

olaf.hartig@liu.se

Types of Failures

Database may become unavailable for use due to:

- Transaction failures
 - e.g., incorrect input, deadlock, incorrect synchronization
 - Result: transaction abort
- System failures
 - e.g., application error, operating system fault
- Media failures
 - e.g., RAM failure, disk head crash, power disruption

Focus of the lecture:

- We wish to recover from system failures
 - Recovery from media failures similar, but may need to restore database files from backup

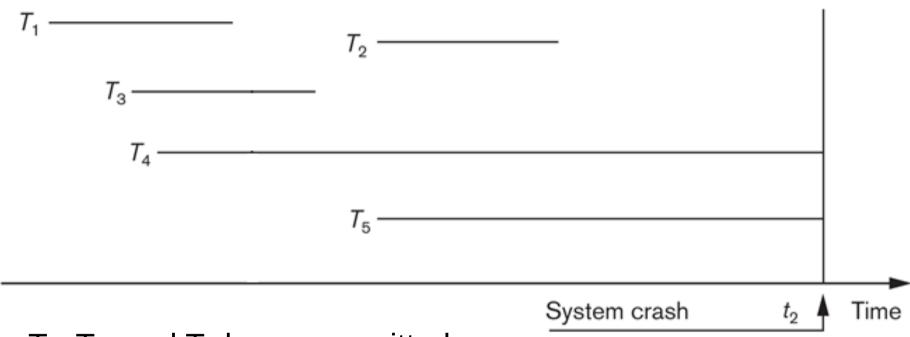

Situation after System Failure

- DBMS is halted abruptly
- Processing of in-progress SQL commands halted abruptly
- Connections to application programs (clients) are broken
- States of executing programs unknown
- Contents of memory buffers are lost
- Database files are not damaged

Problem Situation Example

- T₁, T₂, and T₃ have committed
- T₄ and T₅ still in progress
- Any of the transactions might have written data
- Some (unknown) subset of the writes have been flushed to disk

Purpose of Database Recovery

- Bring the database into the most recent consistent state that existed prior to a failure
- Atomicity and Durability of the ACID properties
 - Abort (and restart) TAs active at time of failure
 - Ensure changes made by committed TAs are not lost
- Complication due to database execution model:
 - Data items packed into I/O blocks (pages)
 - At time of write, updated data first stored in main memory buffer
 - Actually written to disk some time later

Logging

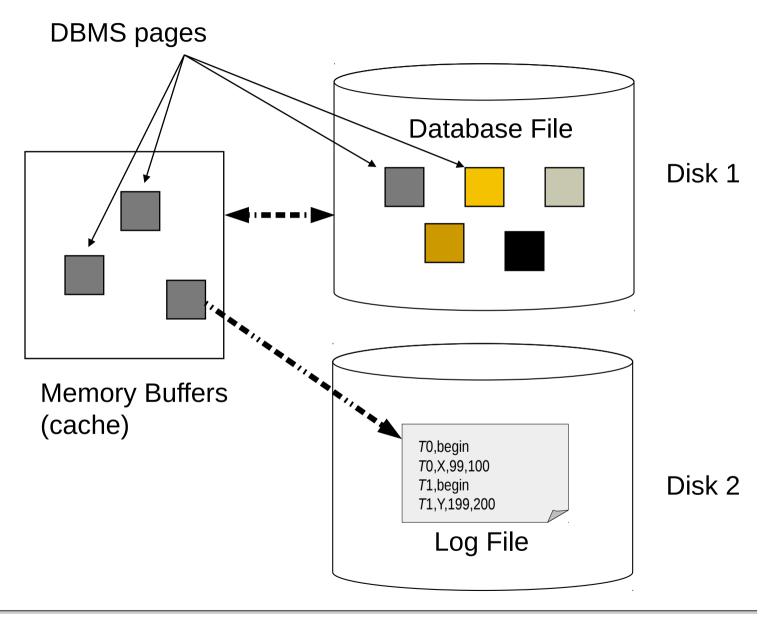

System Log

- Append-only file
 - Keep track of all write operations of all transactions
 - In the order in which these operations occurred
- Stored on disk
 - Persistent except for disk or catastrophic failures
 - Periodically backed up (to guard against disk and catastrophic failures)
- Log buffer in main memory
 - Holds log records that are appended to the log
 - Occasionally whole buffer appended to end of log file on disk (flush)

Storage Structure

Log Records

- [start_transaction, T]
 - Transaction T has started execution
- [write_item, T, X, old_value, new_value]
 - Transaction T has changed the value of item X from old value to new value
 - old_value (before image) needed to undo(X)
 - new_value (after image) needed to redo(X)
- [commit, T]
 - T has completed successfully and committed
 - Effects (writes) of T must be durable
- [abort, *T*]
 - T has been aborted
 - Effects (writes) of *T* must be ignored and undone

Write-Ahead Logging (WAL)

- Used to ensure that the log
 - is consistent with the DB, and
 - can be used to recover the DB to a consistent state
- Two rules:
- 1. Log record(s) for a page must be written before corresponding page is flushed to disk
 - hence, each operation is known and can be undone if needed (important for atomicity)
- 2. All log records of a TA must be written before we consider this TA to be completed successfully
 - hence, the effect of a successfully completed TA is known completely (important for durability)

Commit Point

- A transaction reaches its commit point when:
 - 1. all of its operations are executed, and
 - 2. all its log records are flushed to disk (where the last is the commit record)

- Beyond its commit point
 - the transaction is said to be *committed*, and
 - its effect must be permanently recorded in the DB

Update Strategies and the Corresponding Recovery Process

Recovery with Deferred Update

Updating the DB on disk after each change is inefficient

Deferred update:

- Updates of a transaction T are written to disk after (but not necessarily immediately after) T has reached commit point
- No need to undo changes of non-committed transactions
- Need to redo the changes of committed transactions

NO-UNDO/REDO recovery algorithm:

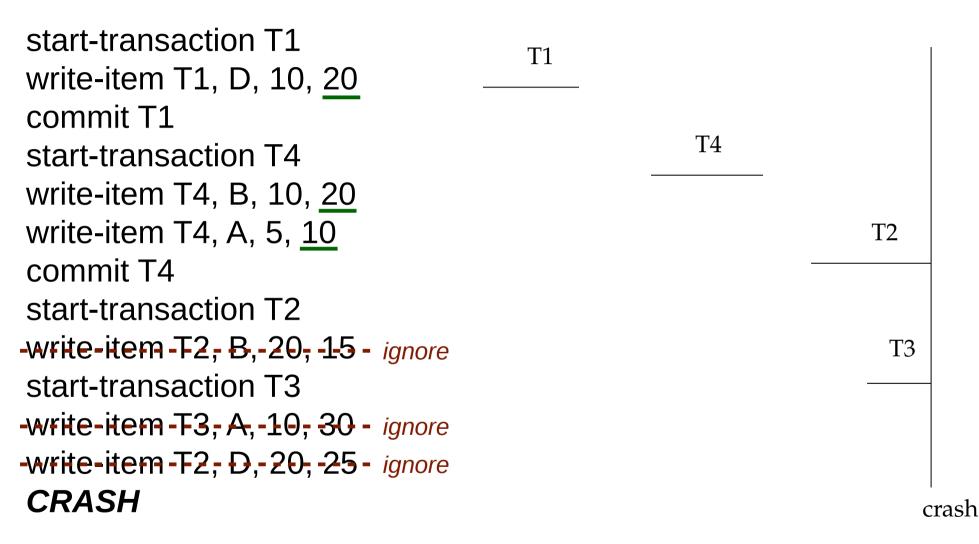

- Create a list of committed transactions
- REDO all the write-item operations of all the TAs in this list in the order in which they appear in the log (use after image from the log records)

Example

NO-UNDO

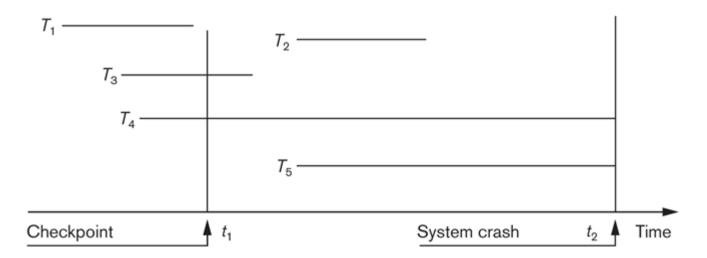

REDO: T1, T4

Checkpointing

- To save redo effort, use checkpoints
- Occasionally flush data buffers using the five steps:
 - 1. Suspend execution of transactions temporarily
 - 2. Force-write modified buffer data to disk
 - 3. Append [checkpoint] record to log
 - 4. Flush log to disk
 - 5. Resume normal transaction execution
- During recovery, redo required only for TAs whose [commit] record appears after the [checkpoint] record

Recovery w/ Deferred Update & Checkpoints

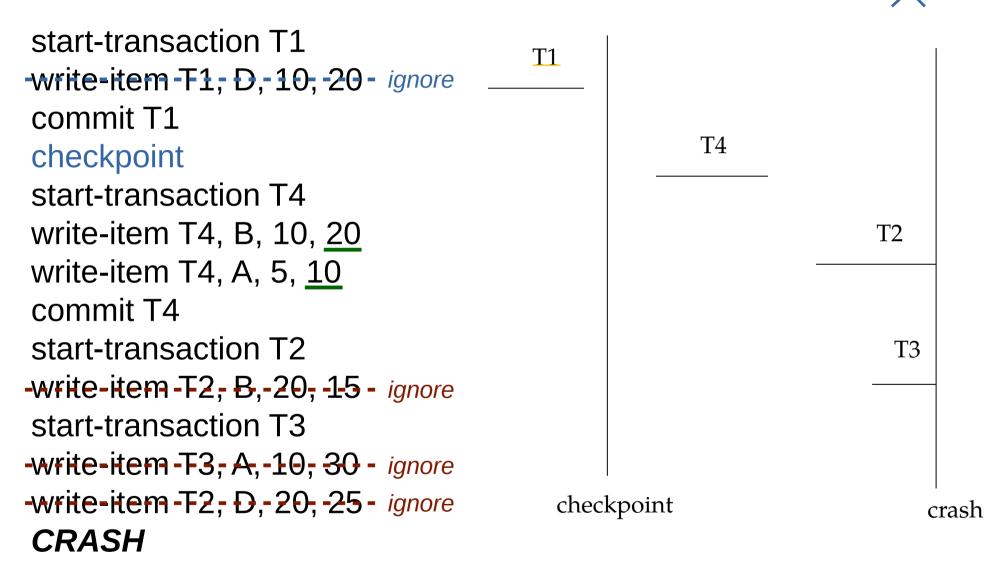

NO-UNDO/REDO recovery algorithm:

- Create a list of committed transactions that have committed after the last checkpoint (note that these transactions may have started before the checkpoint; we have to redo *all* of its operations)
- REDO all the write-item operations of all the TAs in this list in the order in which they appear in the log (use after image from the log records)

Example with Checkpoint

Recovery with Immediate Update 1

• Immediate update:

- Updates of a transaction may be written to disk before the transaction commits (with the log records for such updates being written out first, i.e., write-ahead logging)
- Additional requirement: all updates of a transaction T must be written to disk before the commit point of T
 - No need to redo changes of committed transactions
 - Need to undo changes of non-committed transactions

UNDO/NO-REDO recovery algorithm:

- Create a list of active (i.e., non-committed) transactions
- UNDO all the write-item operations of all the TAs in the list in the reverse order in which they appear in the log (use before image from the log records)

Example

UNDO: T2, T3

NO REDO

start-transaction T1 T1 -write-item-F1, D,-10, -20 - ignore commit T1 T4 -checkpoint---- not needed start-transaction T4 -write-item-T4, B, 10, -20- ignore T2 -write-item-T4, A,-5, 10 - - ignore commit T4 start-transaction T2 T3 write-item T2, B, 20, 15 start-transaction T3 write-item T3, A, 10, 30 write-item T2, D, 20, 25 crash CRASH

Recovery with Immediate Update 2

• Like Immediate Update 1 w/o the additional requirement

Then:

- Need to redo changes of committed transactions
- Need to undo changes of non-committed transactions

UNDO/REDO recovery algorithm:

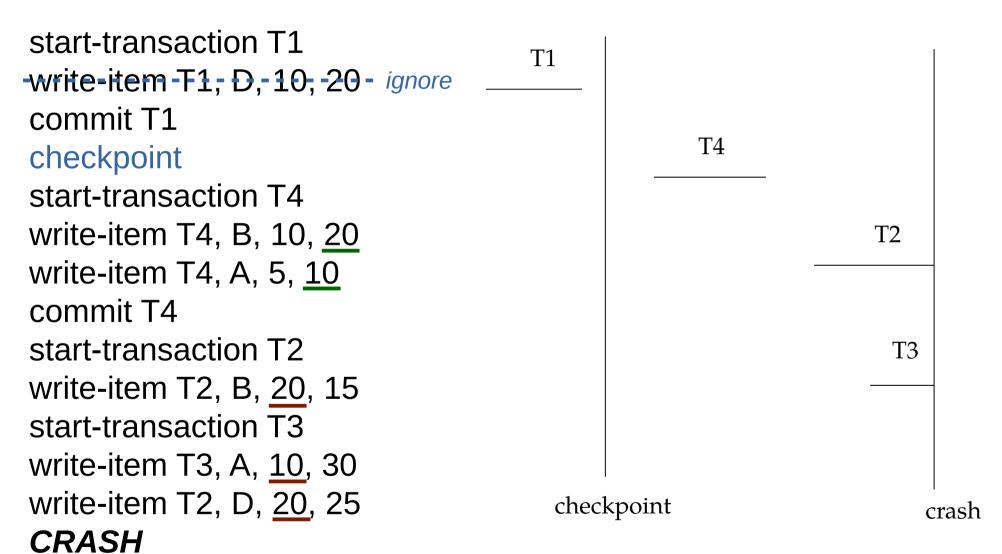

- Create a list of active (i.e., non-committed) transactions, and a list of committed transactions *since last checkpoint*
- UNDO all the write-item operations of all the TAs in the first list in the reverse order in which they appear in the log (use before image from the log records)
- REDO all the write-item operations of all the TAs in the second list in the order in which they appear in the log (use after image from the log records)

Example

UNDO: T2, T3

REDO: T4

Quiz

Which of the following log records include operations that must be *undone* in case of a crash?

Log Seq #	TID	Ор	Item	Before Image	After Image
1	T1	Begin			
2	T1	Write	X	100	200
3	T2	Begin			
4	T2	Write	Υ	50	100
5	Т3	Begin			
6	T1	End			
7	T1	Commit			
8	Т3	Write	Υ	100	300

A: all of them **B:** none of them **C:** 2, 4, 8 **D:** 3, 4, 5, 8 **E:** 4, 8

Summary

Summary

- Transaction log
- Transaction roll-back (undo) and roll-forward (redo)
- Checkpointing
